Autonomic Computing Problem Statement

The Autonomic Computing Initiative

Solution

Self-Management: Systems capable of managing themselves

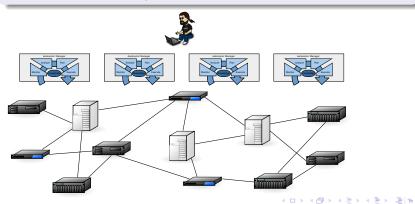

Autonomic Computing Problem Statement

The Autonomic Computing Initiative

Solution

Use Autonomic Managers

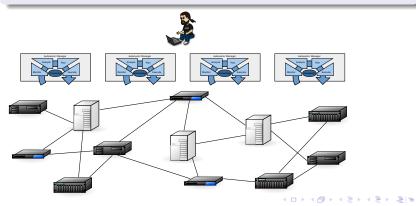

Autonomic Computing Problem Statement

The Autonomic Computing Initiative

Open Question

How to achieve Self-Management?

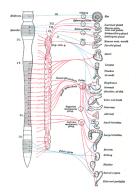

Self-Management for Large Scale Distributed Systems (A. Al-Shishtawy)

Autonomic Computing Problem Statement

Self-* Properties

- Inspired by the autonomic nervous system of the human body
- Control loops from Control Theory
- Self-management along four main axes (self-* properties):
 - self-configuration
 - self-optimization
 - self-healing
 - self-protection

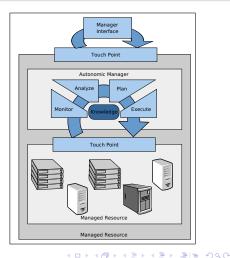

《曰》《曰》《曰》《曰》《曰》 [2]님!

Autonomic Computing Problem Statement

The Autonomic Computing Architecture

- Managed Resource
- Touchpoint (Sensors & Actuators)
- Autonomic Manager
 - Monitor
 - Analyze
 - Plan
 - Execute
- Knowledge Source
- Communication
- Manager Interface

Autonomic Computing Problem Statement

Problem Statement

Large-scale distributed systems

- Complex and require self-management
- May run on unreliable resources
- Major sources of complexity:
 - Scale (resources, events, users, ...)
 - Dynamism (resource churn, load changes, ...)

Goal

- A platform (concepts, abstractions, algorithms...) that facilitates development of self-managing applications in large-scale and/or dynamic distributed environment.
- A methodology that help us to achieve self-management.

Autonomic Computing Problem Statement

Problem Statement

Large-scale distributed systems

- Complex and require self-management

Component Model

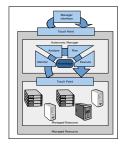

- Architectural approach to autonomic computing
- Applications built of components
- Improved manageability through introspection and reconfiguration
- The Fractal component model

Niche Overview Functional Part Management Part Touchpoints Runtime Environment

Niche

- Niche is a Distributed Component Management System
- Niche implements the Autonomic Computing Architecture
- Niche targets large-scale and dynamic distributed environment and applications
 - Resources and components are distributed
 - Autonomic managers are distributed network of Management Elements (MEs)
 - Sensors and Actuators are distributed

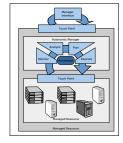

▲ ■ ▶ ▲ ■ ▶ ■ ■ ■ ● Q @

Niche Overview Functional Part Management Part Touchpoints Runtime Environment

- Niche leverages Structured Overlay Networks (SONs) for communication and for provisioning of basic services
 - Name based communication and bindings
 - DHT, Publish/Subscribe, Groups, ...
- Niche separates functional part from management part of the application

Niche Overview Functional Part Management Part Touchpoints Runtime Environment

Functional Part

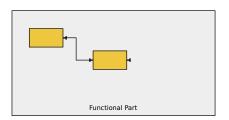

- Components, Interfaces, and Bindings
- System wide identification
- Support for mobility
- Component groups
- One-to-all and one-to-any bindings
- Dynamic group membership
- Deployment using ADL

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

Distributed Management Use Case: YASS

Distributed Management

- In distributed environments we advocate for distribution of management functions among several cooperative managers
- Multiple managers are needed for scalability, robustness, and performance and also useful for reflecting separation of concerns
- Need guidance on how to design distributed management

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

◆□▶ ◆□▶ ◆三▶ ◆三▶ ●|= ◇◇◇

Policies Robust Management Elements

Policy-based Management

- Self-management under guidelines defined by humans in the form of management policies
- Management policy
 - A set of rules that govern the system behaviors
 - Reflects the business goals and/or management objectives

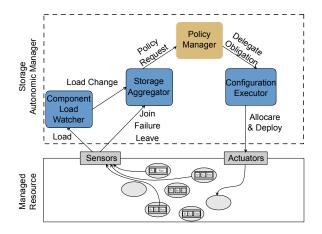

Policies Robust Management Elements

Drawbacks of "Hard-coded" Policy

- Application developer has to be involved in policy implementation
- Hard to trace policies
 - Policies are "hard-coded" (embedded) in the management code of a distributed system
 - Policy logic is scattered in implementation
- Change of policies may requires rebuilding and redeploying of the application (or at least its management part)

Policies Robust Management Elements

Example: YASS Self-Configuration Using Policies

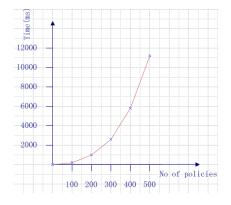

Policies Robust Management Elements

Policy Languages (used in this work)

Migration: Basic Idea

- A configuration is the set of replicas
- Replicas include the configuration as part of the state
- A special request that changes the configuration
- Handled like normal requests (assigned a slot then executed)
- The change take effect after α slots
- We used the SMART algorithm Details

Policies Robust Management Elements

Our Algorithm

Goals

- Automatically maintain configuration in a decentralized way
- Select resources, detect failures, and decide to migrate
- Users find service without central repository

Approach

- We use Structure Overlay Networks(SONs)
- We use replica placement schemes (such as symmetric replication) to select nodes that will host replicas
- We use lookups and DHT ideas
- We use failure detection provided by SONs

Creating a Replicated State Machine (RSM)

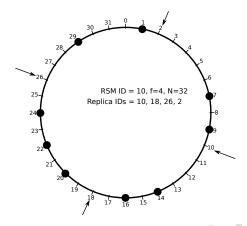

Any node can create a RSM. Select ID and replication degree

Policies Robust Management Elements

Creating a Replicated State Machine (RSM)

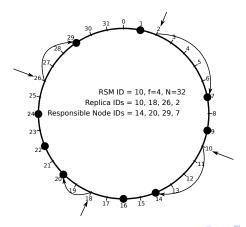

The node uses symmetric replication to calculate replica IDs

Policies Robust Management Elements

Creating a Replicated State Machine (RSM)

The node use lookups to find responsible nodes

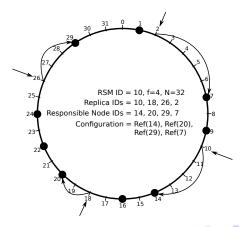

ъ

Policies Robust Management Elements

Creating a Replicated State Machine (RSM)

... and gets direct references to them

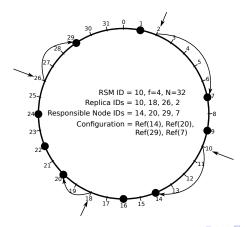

-∃=->

Policies Robust Management Elements

Creating a Replicated State Machine (RSM)

The set of direct references forms the configuration

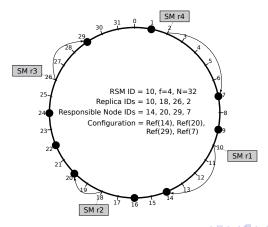

ъ

Policies Robust Management Elements

Creating a Replicated State Machine (RSM)

The node sends a Create message to the configuration

.⊒...>

Policies Robust Management Elements

Creating a Replicated State Machine (RSM)

Now replicas communicate directly using the configuration

Replica Architecture

Policies Robust Management Elements

When to Migrate?

- To fix Lookup inconsistencies
- To handle resource churn

Self-Management for Large Scale Distributed Systems (A. Al-Shishtawy)

◆□ → ◆□ → ◆ □ → ◆ □ → ◆ □ → ◆ ○ ◆

Policies Robust Management Elements

Handling Lookup Inconsistency

- Because of lookup inconsistency the configuration may contain incorrect nodes
- The inconsistency is detected when a node receives a request targeted at a replica that the node does not have but should be responsible for
- In this case the node issues a configuration change request asking the current configuration to replace the incorrect node with itself

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

Policies Robust Management Elements

Handling Churn

- Similar to handling churn in a DHT
 - When a node joins it gets a list of replicas (RSM_ID and rank) it is responsible for form its successor
 - When a node leaves it hand over replicas to its successor
 - When a node fails the successor uses symmetric replication and interval cast to find replicas it should be responsible for
- After getting the list of replicas the node issue a configuration request to each RSM to replace incorrect node with itself

Policies Robust Management Elements

Changing the Configuration (Migration)

- In SMART the admin sends a configuration change request that contains all nodes in the new configuration
- We can not do the same in a decentralized fashion to avoid conflicts

Example

- Assume current configuration is {A, B, C, D}
- Node X detects that C is dead and requests change to {A, B, X, D}
- Node Y detects that D is dead and requests change to {A, B, C, Y}
- Y overrides the change made by X!

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

Policies Robust Management Elements

Changing the Configuration (Migration)

 In our approach the request does not contain the entire configuration. It contain only a request to replace a particular node

Example

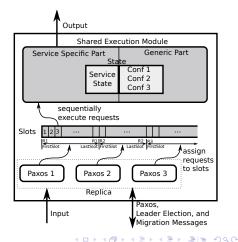

- Assume current configuration is {A, B, C, D}
- Node X detects that C is dead and requests replacing replica 3 with itself
- Node Y detects that D is dead and requests replacing replica 4 with itself
- The end result is {A, B, X, Y}

Policies Robust Management Elements

Robust Management Elements

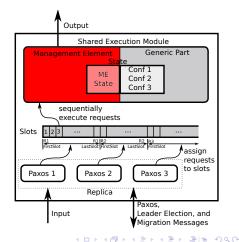

- Our approach is generic and can be useful for many services
- We use it in Niche to implement Robust Management Elements
- Replace the service specific part of the execution module with a management element

Conclusions Future Work

Future Work

- Refine design methodology including steps and interaction patterns
- Consider more use cases focusing on real applications
- Study and investigate management patterns and techniques
 - Distributed control, distributed optimization
 - Model Predictive Control (MPC)
 - Reinforcement learning in (feedback) control
 - Networked Control System (NCS)
- Focus more on self-tuning
- Complete work on Robust Management Elements
- Port Niche to Kompics component model

Migration: The SMART Algorithm

- SMART is a new technique for changing the set of nodes (configuration) where a replicated service runs (i.e. migrating the service)
- Advantages over other approaches (as described by SMART authors):
 - Allows migrations that replace non-failed nodes (suitable for automated service)
 - Can pipeline concurrent requests (performance optimization)
 - Provides complete description

<ロ> <同> <同> < 回> < 回> < 回> < 回</p>

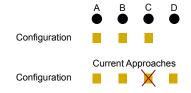

Configuration-Specific Replicas

- Each replica is associated with one and only one configuration
- Migration creates a new set of replicas (configuration)
- Simplifies the migration process
- Each configuration uses its own instance of the Paxos algorithm
- Inefficient implementation (use shared execution module to improve it)

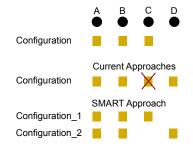

Configuration-Specific Replicas

- Each replica is associated with one and only one configuration

- Migration creates a new set of replicas (configuration)
- Simplifies the migration process
- Each configuration uses its own instance of the Paxos algorithm
- Inefficient implementation (use shared execution module to improve it)

<ロ> <同> <同> < 回> < 回> < 回> < 回</p>

SMART

- Avoids inter-configuration conflicts by assigning none overlapping range of slots [*FirstSlot*, *LastSlot*] to each configuration
- The old configuration sends a Join message to the new configuration
- A replica in a new configuration need to copy state from another replica (up till at least *FirstSlot* – 1)
- Destroying old configurations (Finished and Ready messages)
- Clients use a configuration repository to find the current configuration
- SMART does not deal with how to select a configuration and when to migrate

Challenges Implementing Lamport's Idea

- Unaware-leader challenge: A new leader may not know the latest configuration
- Window-of-vulnerability challenge: Migrations that remove or replace a machine can create a period of reduced fault tolerance
- Extended-disconnection challenge: After a long disconnection, a client may be unable to find the service
- Consecutive-migration challenge: If request n changes the configuration, requests n + 1 through n + α - 1 cannot change the configuration
- Multiple-poll challenge: A new leader may have to poll several configurations

Return
